

What it does?

Generates Clean Core-compliant SAP ABAP code:

- CDS views,
- AMDP,
- RAP business objects,
- OData/Fiori exposure,
- IDoc retrigger/enhancement,
- Function Modules,
- BADIs,
- Classic ALV/Dynpro/WebDynpro (legacy only),
- Forms,
- Workflow,
- Background jobs,
- Web-service consumption,
- DDIC objects, and more

matched to your actual target SAP system so the first draft compiles and fits, instead of needing several rounds of fixes.

How to start?

Just ask normally

E.g.:

- "Build a RAP BO for sales order approval"
- "Create a CDS view joining VBAK and VBAP with a margin calculation"
- "I need an OData service exposing purchase order approval, S/4HANA Cloud"
- "Fix this AMDP method, it's timing out" (paste the code)

You don't need to name the skill — mentioning ABAP, S/4HANA, CDS, RAP, Clean Core, or BTP ABAP Environment is enough for it to kick in.

What happens next?

1. **A few tappable-button questions** appear in a small widget — things like which environment edition you're on, what scope of change this is, and artifact-specific details. Tap an answer, it moves to the next one automatically. You'll see them labelled "Question 1 of X" so you know how many are left.

2. **A details form** appears next, with text fields and placeholder hints (e.g. namespace prefix, package, requirement description). Fill in what you know — anything left blank gets a clearly-flagged placeholder in the generated code instead of a guess.

You get the generated code back, already checked against Clean Core rules for your declared environment, usually with a matching unit test offered alongside.

Worth having ready before you start:

Target environment: On-Premise / Cloud Private Edition / Cloud Public Edition / BTP ABAP Environment — this is asked every time and impacts what's even legal to generate, so an accurate answer here saves the most rework.

Namespace:

Z or Y prefix, and target package (local \$TMP or a transportable package + transport request, if you have one).

If you're **fixing or enhancing** something: the actual existing code, table/CDS structure, or exact error message. Pasting this is the single biggest time-saver — guessed structures are the most common reason for a second round.

A **custom authorization object** name, if you're checking against one that isn't standard.

Anything you don't have yet — skip it. The flow is designed to keep moving with partial answers.

A few things to know

Questions adapt to your environment automatically — e.g. you won't be asked your Basis release on Cloud Public Edition, and illegal options (like Unmanaged RAP, or classic ALV/Dynpro/WebDynpro) just won't appear as choices once you've picked a cloud edition. If a whole category of work genuinely isn't legal for your edition (e.g. classic Smart Forms under Cloud Public Edition), you'll get a clear note about that plus the modern alternative — not silently-wrong code. "Not sure" is a valid answer on most questions — it just means the skill defaults to the safest, most conservative pattern and says so.

What this skill won't do?

Non-ABAP BTP services — Integration Suite iFlows/Groovy scripting, CAP (Node/Java), Event Mesh, SAP Build Process Automation. ABAP only. Actual role/PFCG user assignment, transport release, or any other Basis/security decision — it'll tell you the steps, but those happen outside ABAP.
